Firebase Authentication with React

Complete visual walkthrough: project setup, authentication provider, and web SDK configuration

After enabling authentication: install the Firebase SDK in your React project with `npm install firebase`, initialize Firebase using the web configuration, and use Firebase Authentication functions to create accounts and sign in.

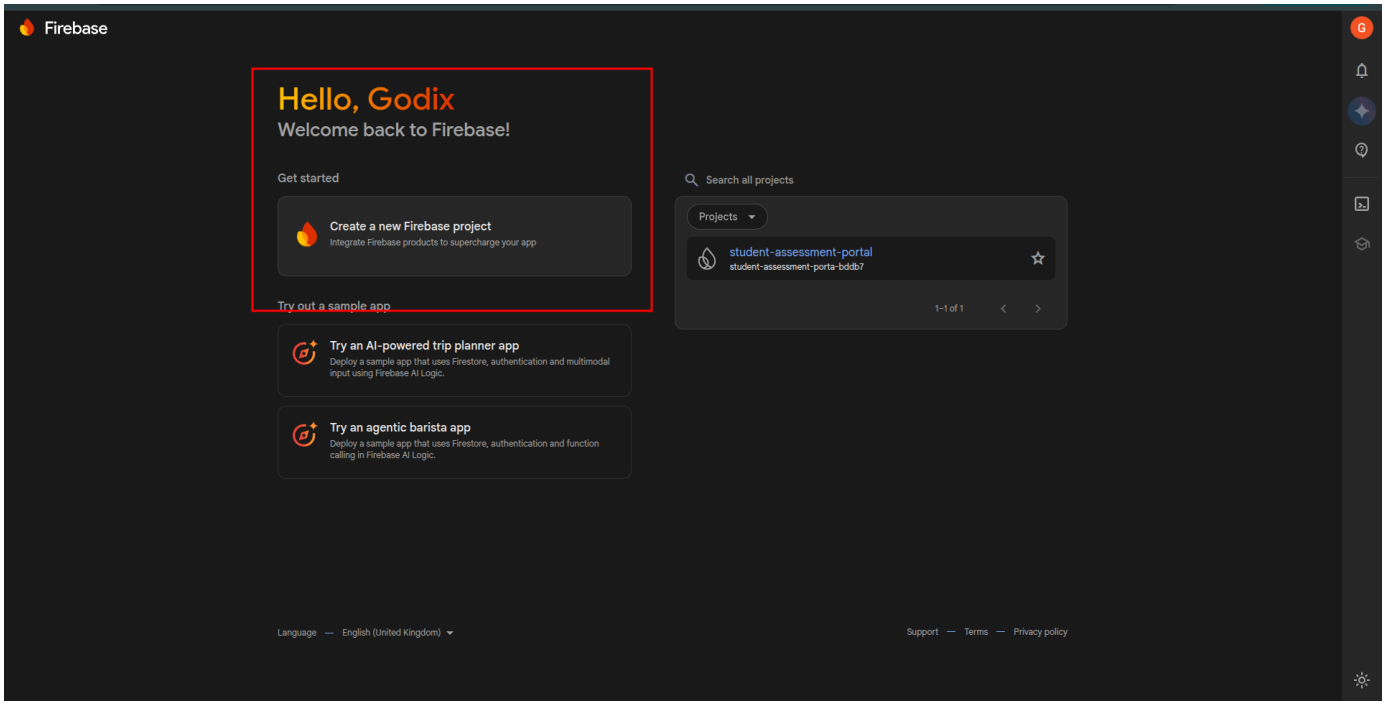

Security reminder: web configuration values are intended for client-side use, but never place service-account keys or private server secrets in React. Protect Firebase data with Security Rules.

1. Create a Firebase project

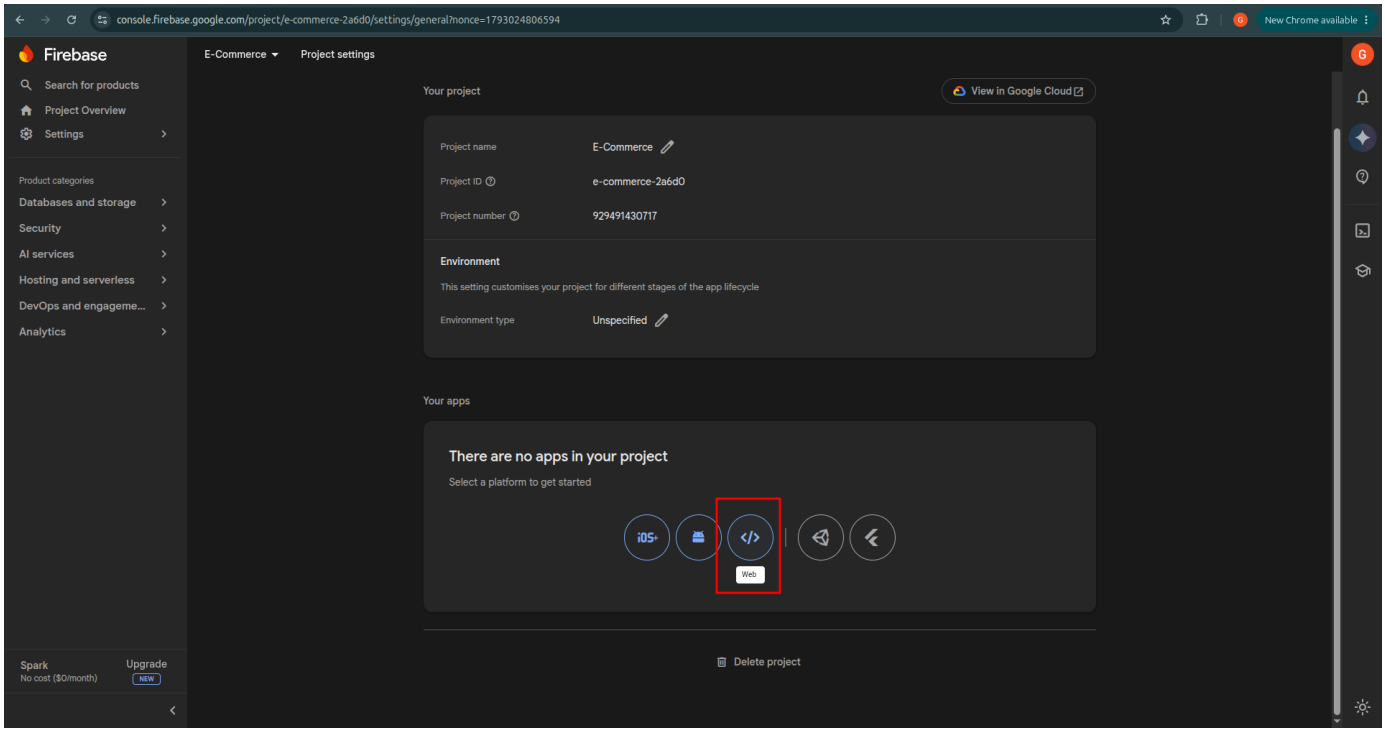

From the Firebase welcome screen, choose “Create a new Firebase project”.

2. Enter the project name

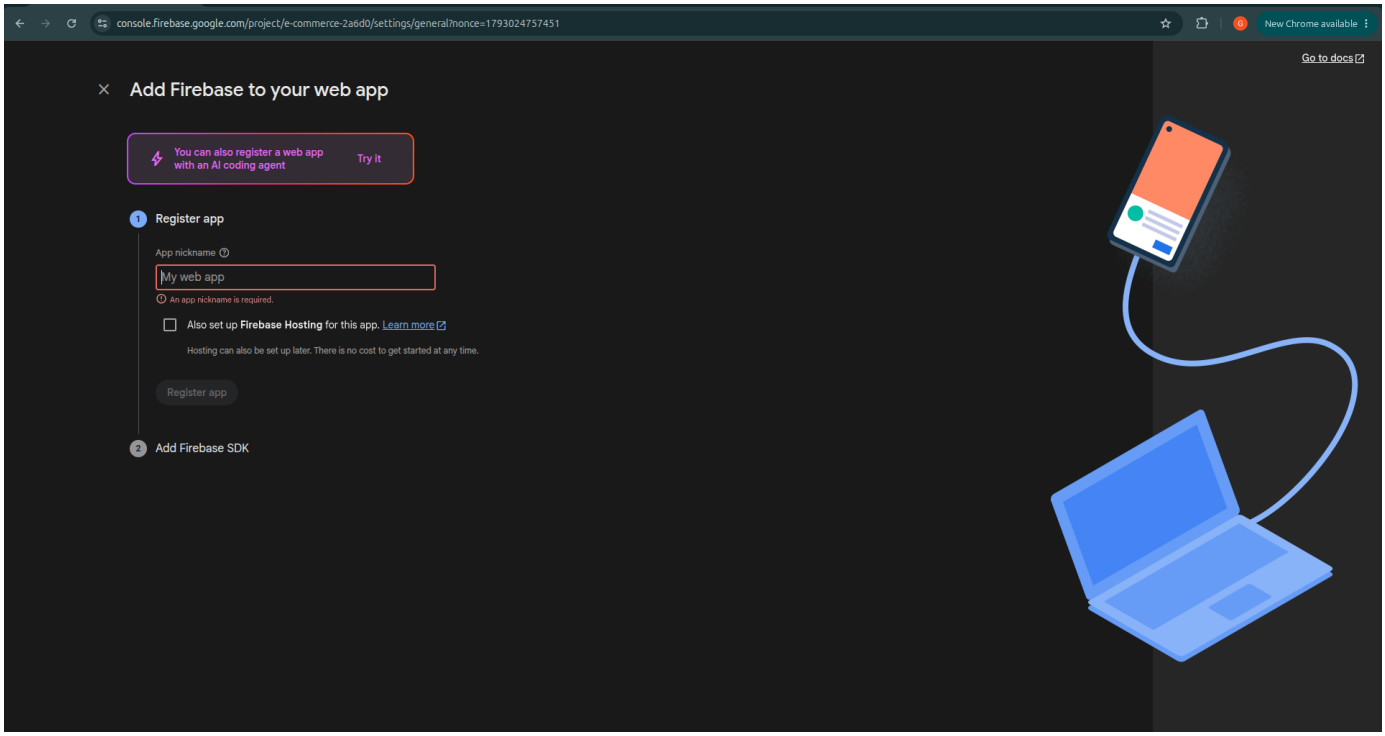

Enter a project name, then follow the prompts to create the project.

3. Register your React web app

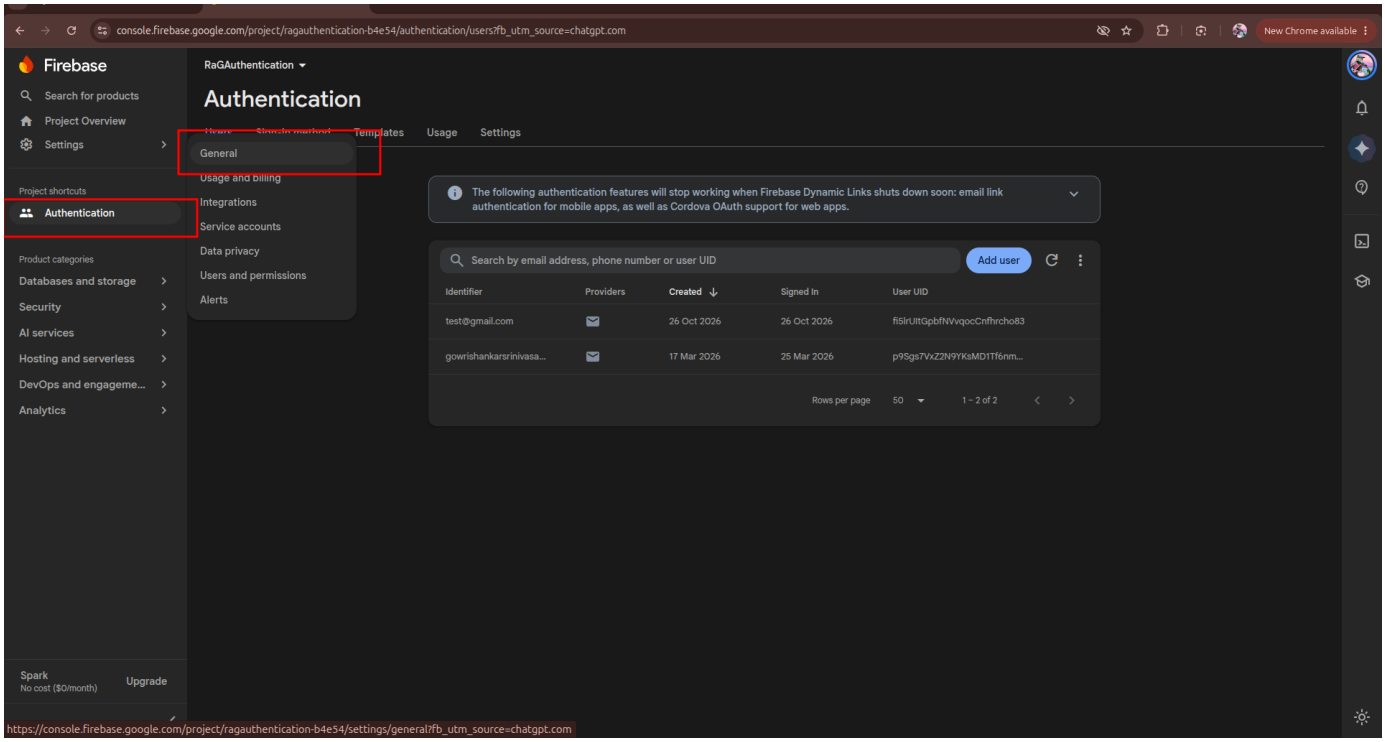

Choose a nickname for your web app. Firebase Hosting is optional for local development.

4. Select the Web app platform

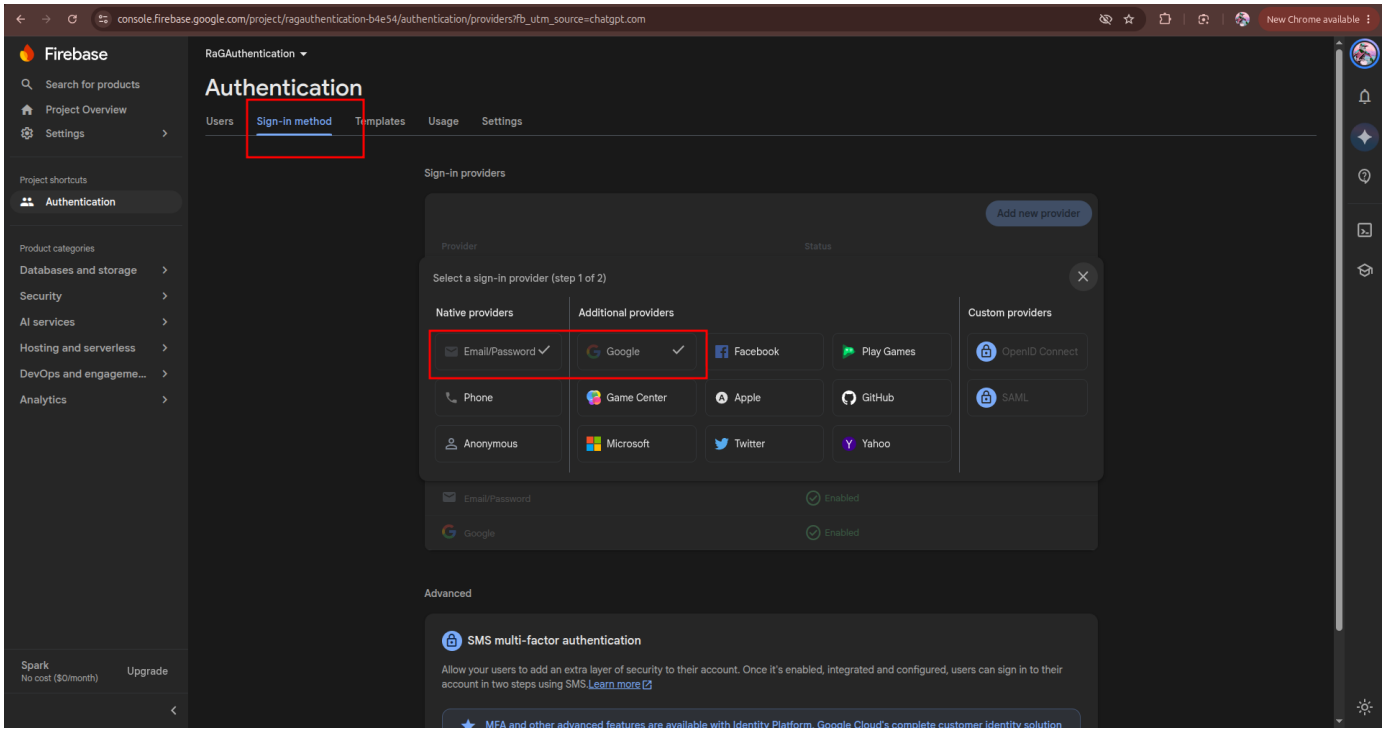

In Project settings, select the Web () icon under “Your apps” to register the app.

5. Open Authentication settings

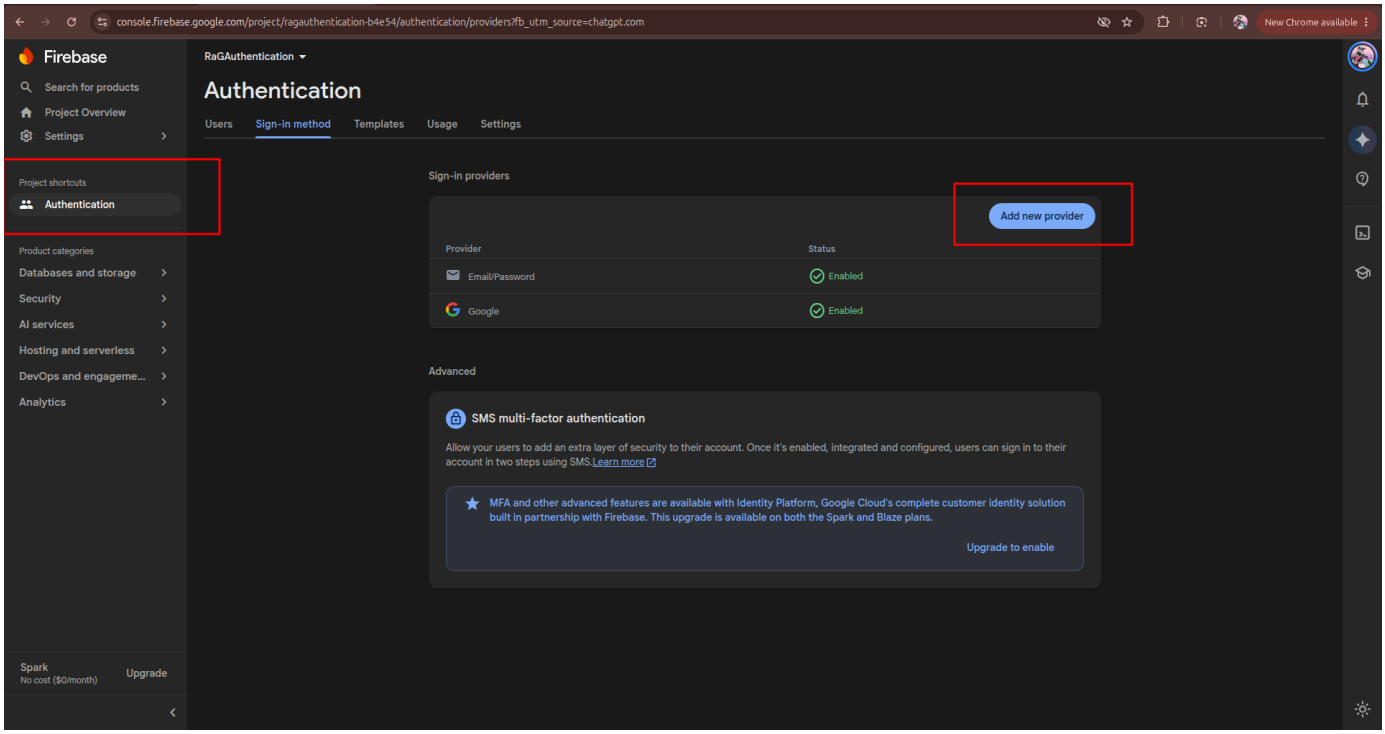

Open Authentication from the left-side Project shortcuts. The Users tab shows registered accounts.

6. Open Sign-in method

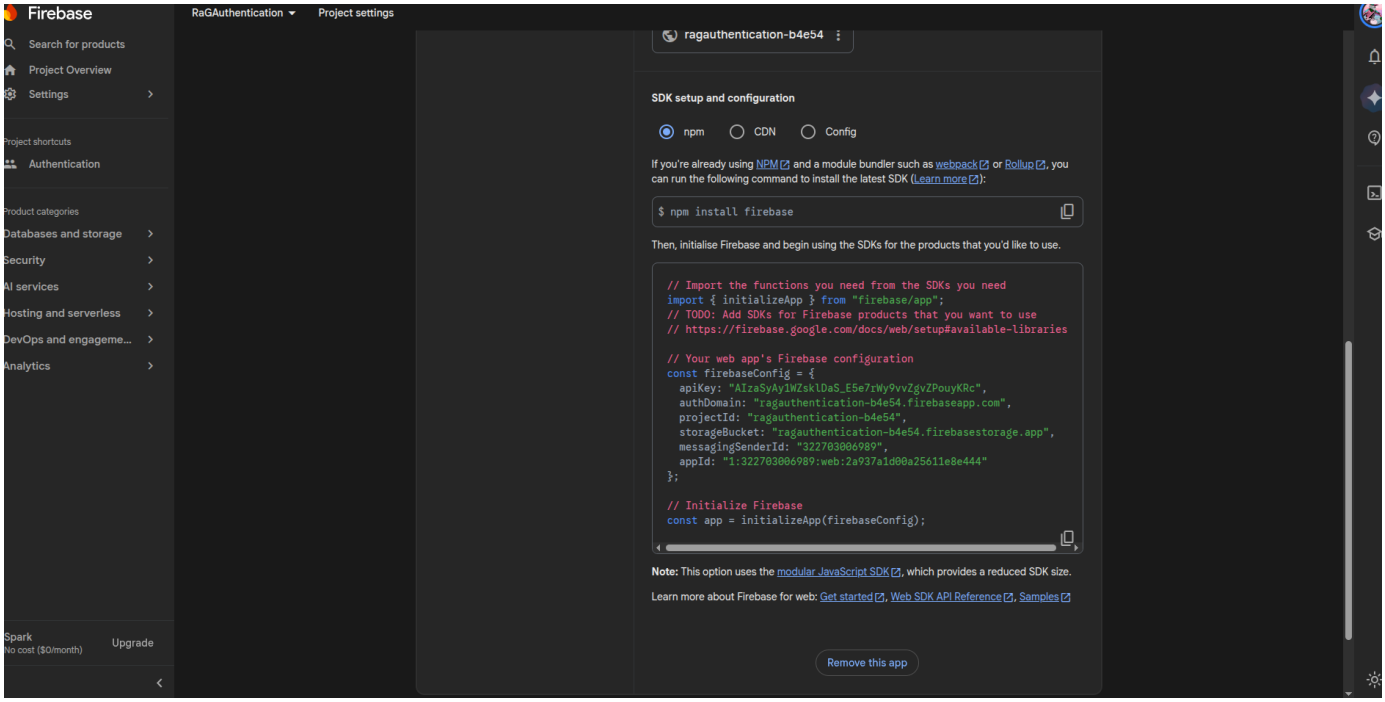

In Authentication, select the “Sign-in method” tab, then choose “Add new provider”.

7. Choose an authentication provider

Select Email/Password to enable email and password sign-in. Google sign-in is optional.

8. Copy the Firebase SDK configuration

In Project settings, find your registered web app and copy the configuration values. Keep these values consistent with your project.
